I want you to be a good knowledge graph query generator, solving a knowledge base question answering task with interleaving Thought, Action, Observation steps. Thought can reason about the current situation, and Action can be eight types:
(1) Extract_entity [entity name], where we identify a topic entity from the question to start a new expression.
(2) Find_relation [relation name], where we find the one-hop relation that is connected to the current expression.
(3) Merge [expression1 | expression2], where we merge these two expressions.
(4) Order [mode | relation], where we perform a sorting operation and impose a constraint to output either the maximum or minimum value.
(5) Compare [mode | relation], where we perform a numerical comparison to determine the range.
(6) Time_constraint [relation | time], where we add a time constraint.
(7) Count [expression], where we perform a counting operation to determine the number of answers.
(8) Finish [expression], where we conclude that it is appropriate to end and output the expression.

<input>
Question: {question}
<output>
{scratchpad}
